CUSTOMER CHURN ANALYTICS REPORT

Baseline churn • Customer lifetime value • MRR at risk • Behavioral drivers

Executive summary

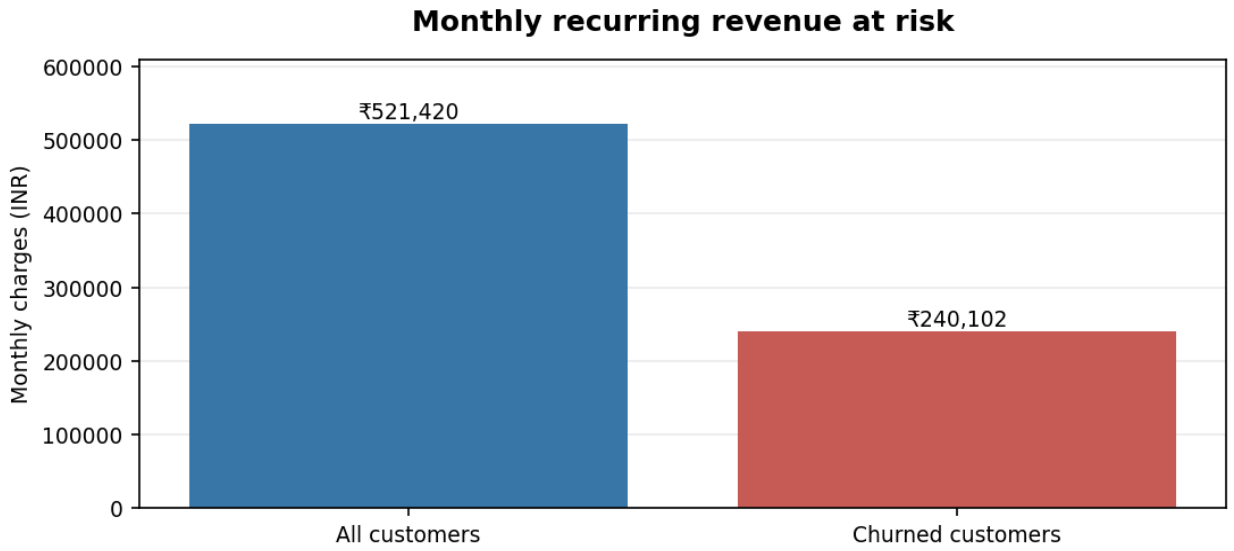

The cleaned analysis dataset contains **600 unique records** after removing 5 exact duplicate rows. **247 customers churned**, giving a baseline churn rate of **41.2%**. The monthly charges associated with churned customers total **■240,102**, approximately **46.0%** of all customers' monthly charges in this dataset. The highest-risk segments are month-to-month contracts (59.8% churn) and customers in their first six months (65.4% churn).

Baseline churn	Revenue-based CLV proxy	Monthly revenue at risk
41.2% 247 of 600 customers	**■30,887** Average monthly charge × average tenure	**■240,102** 46.0% of total monthly charges

Metric definitions and limitations

CLV proxy: average monthly charge (■869) × average observed tenure (35.5 months) = **■30,887** per customer. This is a simple revenue-only estimate, not profit CLV: the dataset has no gross margin, acquisition cost, discount rate, or forward-looking retention model. For context, the mean of valid recorded total charges is ■26,743; 10 total-charge values were nonnumeric/missing after duplicate removal, so this figure is based only on valid values. MRR at risk is the sum of current monthly charges for customers marked churned; it estimates the recurring charges associated with churned records, not necessarily a single month's realized accounting loss.

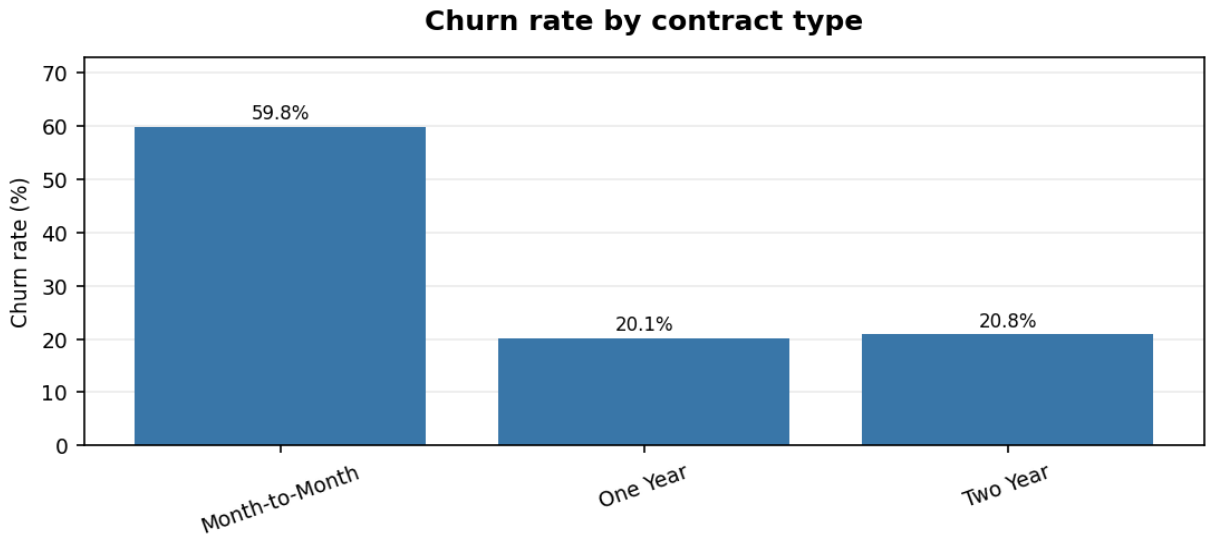

1. Baseline and revenue exposure

Total monthly charges across the 600-record analysis set are ■521,420. Churned customers account for ■240,102 in monthly charges. Because churned customers have higher average monthly charges (■972) than retained customers (■797), churn prevention should consider both customer risk and the revenue value of each account.

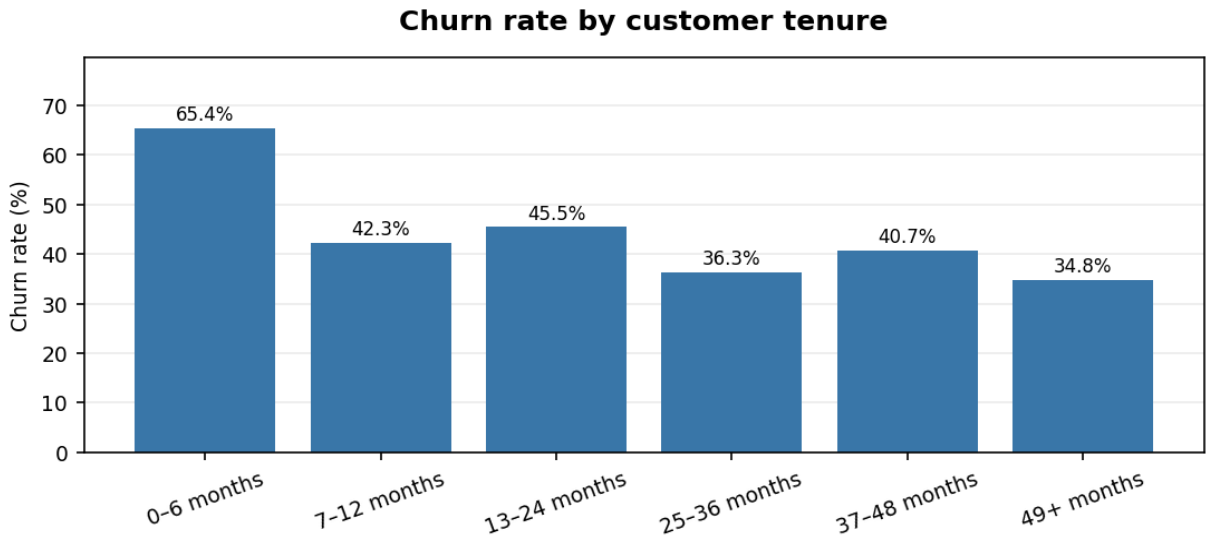

2. Churn by customer segment

Contract type

Finding: Month-to-Month: 59.8% (189/316 customers); Two Year: 20.8% (25/120 customers); One Year: 20.1% (33/164 customers). Month-to-month churn is roughly three times the one-year rate. Contract type is the clearest segment-level risk signal in this dataset.

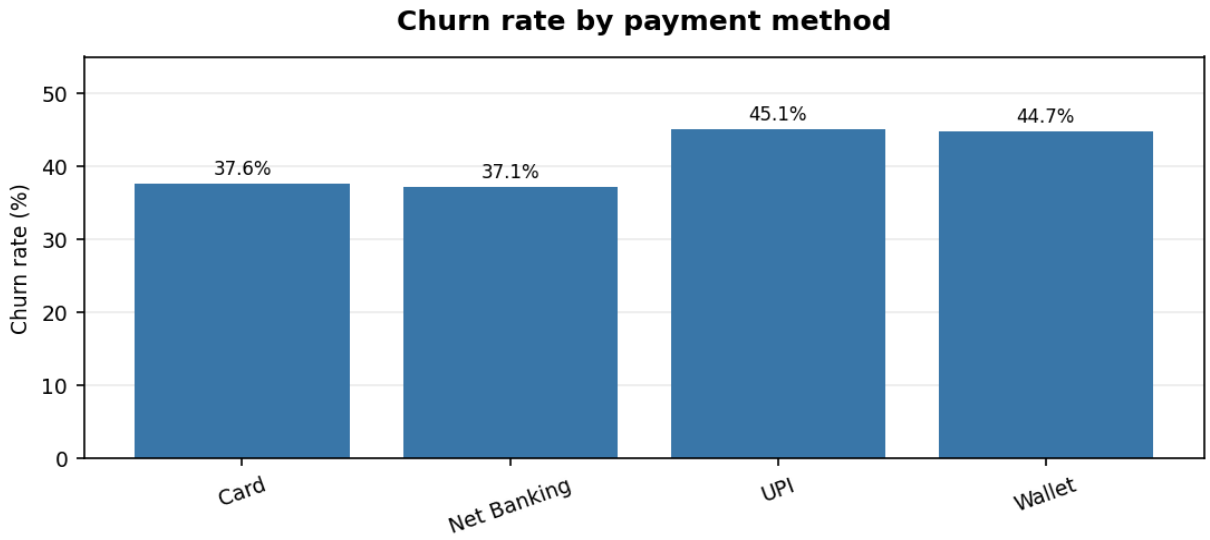

Tenure

Finding: Churn is highest among customers with 0–6 months of tenure (65.4%). The early customer journey is a priority for onboarding, expectation-setting, and proactive support. The 13–24 month band also has elevated churn relative to longer-tenured customers.

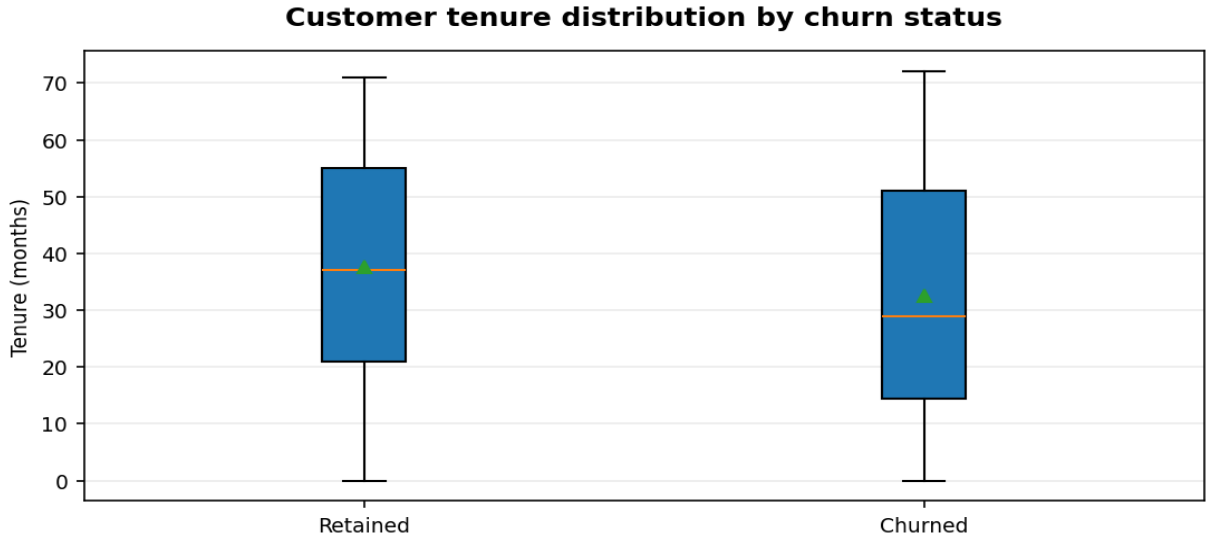

3. Payment behavior and customer tenure

Payment method

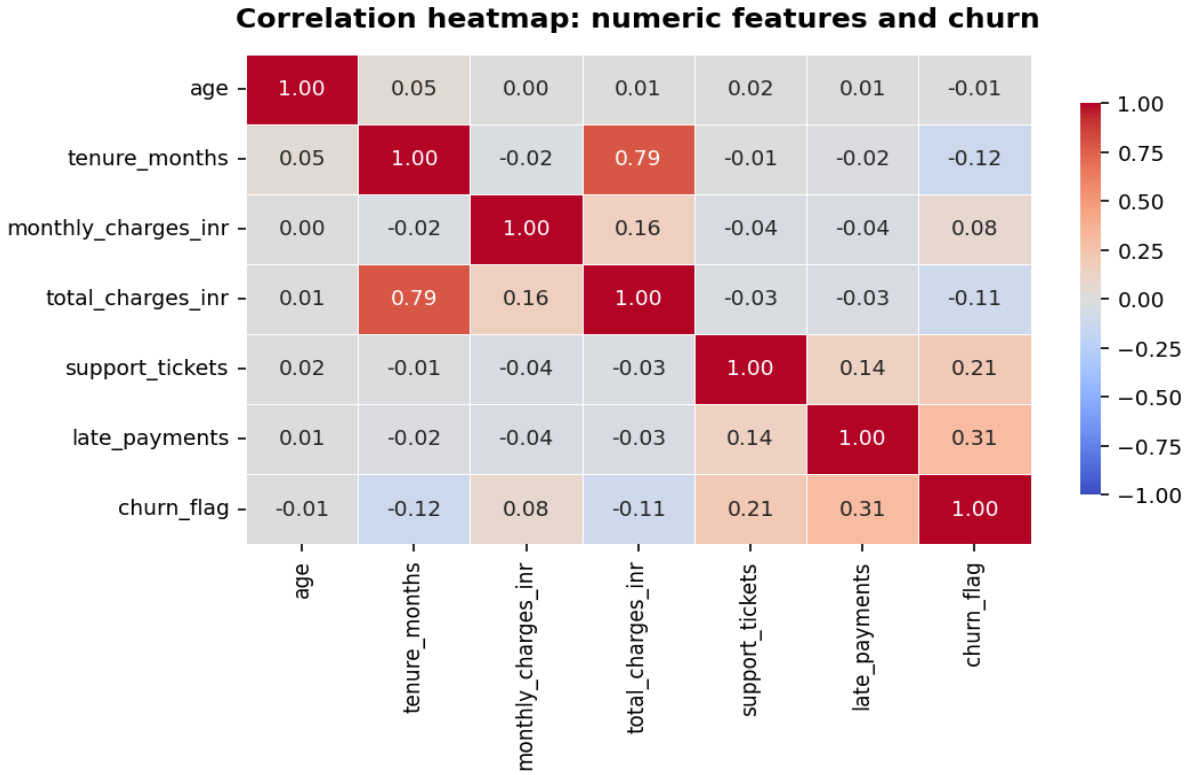

Finding: UPI: 45.1%; Wallet: 44.7%; Card: 37.6%; Net Banking: 37.1%. Wallet and UPI customers have higher observed churn than Card and Net Banking customers. This is an association, not proof that payment method causes churn.

Tenure distribution

Mean tenure is 32.5 months for churned records and 37.6 months for retained records. The overlap in the boxplot indicates tenure alone will not identify every customer at risk; combine tenure with support and payment signals.

4. Behavioral signals and recommendations

The strongest simple numeric associations with churn are **late payments (r = 0.31)** and **support tickets (r = 0.21)**. These are modest correlations and do not establish causation. Use them as candidate early-warning features and validate them on future data.

Actionable recommendations

1. Strengthen first-90-day onboarding — Send setup guidance, check-in messages, and a day-30/day-60 satisfaction survey. Offer proactive help to customers in the 0–6 month band.

2. Reduce month-to-month churn — Test transparent annual-plan incentives, loyalty benefits, or a pause option. Avoid forcing long contracts; compare conversion and retention in a controlled experiment.

3. Intervene after support friction — Trigger a follow-up after repeated support tickets, unresolved cases, or low satisfaction. Track time-to-resolution and repeat-contact rate.

4. Support payment reliability — For customers with late payments, send friendly reminders before due dates, explain failed-payment recovery, and offer secure alternative payment methods.

5. Investigate Wallet and UPI segments — Review payment failures, refund/settlement issues, and customer feedback by method. Run a small targeted test before changing payment flows.

6. Prioritize by risk and revenue — Build a weekly churn-risk list using contract, tenure, late payments, support tickets, and monthly charges. Estimate save-rate and retained revenue from intervention tests.

Measurement plan

Track monthly churn rate, early-tenure churn, month-to-month churn, payment failure/late-payment rate, support resolution time, and MRR retained through save offers. Use a holdout group or A/B test to distinguish real impact from normal variation.

5. Data quality and methodology

Input size: 605 rows. Removed 5 exact duplicate records, leaving 600 records. Region had 13 missing values; 10 TotalCharges values could not be parsed as numbers. The churn and segment analyses use the de-duplicated records. The report does not impute total charges because CLV is calculated from monthly charges and observed tenure; valid

recorded total charges are reported only as context. Missing region is not used to make the primary segment claims. No date columns were present.

Conclusion

The data points to three immediate priorities: improve retention in the first six months, reduce avoidable churn among month-to-month customers, and intervene when payment or support problems appear. The revenue exposure is material, so retention actions should be tested and measured against MRR retained rather than relying on churn-rate changes alone.
